ABSTRACT

Background: Ayurveda describes Sapta Dhatu as seven fundamental constituents that sustain the structure and physiological functions of the human body: Rasa, Rakta, Mamsa, Meda, Asthi, Majja, and Shukra. Modern histology studies the microscopic structure of cells, tissues, and organs. **Aim:** To review Sapta Dhatu according to classical Ayurvedic literature and critically compare it with modern histology. **Materials and Methods:** This narrative review draws on classical texts, including Charaka Samhita and Sushruta Samhita, published literature, and standard histology references. Descriptions of the seven Dhatus were compared with relevant modern tissue categories. **Discussion:** Ayurvedic literature describes the Dhatus as structural and functional constituents of the body. Modern histology classifies tissues by cellular composition, extracellular matrix, microscopic architecture, and physiological function. Some similarities can be discussed, but the two systems use different conceptual frameworks and no universal one-to-one correspondence is established. **Conclusion:** Sapta Dhatu Siddhanta is important in Ayurvedic Rachana Sharir. Critical comparison can support interdisciplinary understanding while preserving the distinction between traditional concepts and experimentally established tissue classifications.

KEYWORDS: Sapta Dhatu, Rasa Dhatu, Rakta Dhatu, Mamsa Dhatu, Meda Dhatu, Asthi Dhatu, Majja Dhatu, Shukra Dhatu, Histology, Ayurveda.

1. INTRODUCTION

Ayurveda describes the human body through the fundamental concepts of Dosha, Dhatu, and Mala. Dhatus are considered essential constituents that support the body and contribute to its maintenance, nourishment, and functioning.[1–3]

The seven Dhatus are Rasa, Rakta, Mamsa, Meda, Asthi, Majja, and Shukra. Their formation, nourishment, functions, and relationship with bodily condition are discussed in the Brihattrayi: Charaka Samhita, Sushruta Samhita, and Ashtanga Hridaya.[1–3]

Modern histology is the biomedical study of the microscopic structure of tissues, including cellular organization, extracellular materials, tissue architecture, and structure–function relationships.[5–7]

Comparing Sapta Dhatu with modern histology offers an opportunity to examine similarities and differences. Care is needed because the Ayurvedic term Dhatu encompasses broader structural and functional meanings than the modern histological category of tissue.[1–3]

2. AIM AND OBJECTIVES

Aim

To review Sapta Dhatu Siddhanta according to Ayurveda and critically compare it with modern histology.

Objectives

- To describe Sapta Dhatu according to classical Ayurvedic literature.[1–3]
- To review the major functions attributed to each Dhatu.[1–3]
- To identify relevant modern histological structures for comparison.[5–7]
- To discuss similarities and differences between Ayurvedic and modern concepts.
- To identify research gaps for future interdisciplinary studies.

3. MATERIALS AND METHODS

The present article is a narrative review based on classical Ayurvedic literature and contemporary histological references. Principal sources included:

- Charaka Samhita, especially sections concerning Dhatu, Dhatu Poshana, and Dhatu Sara.[1]
- Sushruta Samhita, particularly Sutra Sthana and Sharira Sthana passages concerning Dhatu and bodily structure.[2]
- Ashtanga Hridaya sections describing Dhatu and their functions.[3]
- Standard histology textbooks and educational resources.[5–7]
- A published review of Dhatu Nirmana Prakriya in Charaka Samhita and Sushruta Samhita.[4]

The seven Dhatus were reviewed individually. Traditional descriptions were compared with modern tissue categories according to structural and functional characteristics. These comparisons are interpretative and are not treated as proof of direct equivalence.

4. Concept of Sapta Dhatu in Ayurveda

The term Dhatu is associated with the idea of supporting or sustaining. In Ayurveda, Dhatus are described as fundamental constituents that maintain the body.[1–3]

The seven Dhatus are Rasa, Rakta, Mamsa, Meda, Asthi, Majja, and Shukra.[1–3]

Classical Ayurvedic texts discuss Dhatu formation and nourishment through concepts such as Dhatu Poshana and Dhatvagni. Explanatory models include Ksheera-Dadhi, Kedari-Kulya, and Khale-Kapota Nyayas.[1–4] These belong to the traditional physiological framework; comparison with modern metabolism requires attention to differences in terminology and explanatory methods.

5. Comparative Review of Individual Dhatus

5.1 Rasa Dhatu

Ayurvedic perspective: Rasa Dhatu is traditionally associated with nourishment and maintenance of bodily tissues. It is described as a product of digestion and related to the transport of nourishment throughout the body.[1–3]

Modern histological perspective: Modern biology does not recognize a single tissue equivalent to Rasa Dhatu. Depending on the classical passage, possible points of comparison include circulating plasma, extracellular fluid, lymph, and nutrient transport. Plasma contains water, proteins, electrolytes, nutrients, hormones, and other dissolved substances; lymph and interstitial fluid have distinct compositions and functions.[5–7]

Comparative interpretation: Rasa Dhatu and nutrient distribution have a broad functional point of comparison. Rasa Dhatu should not be equated exclusively with plasma, lymph, or any one modern body fluid.[1–3, 5–7]

5.2 Rakta Dhatu

Ayurvedic perspective: Rakta Dhatu is associated in classical texts with life, nourishment, and complexion; its formation and relationship with health and disease are also discussed.[1–3]

Modern histological perspective: Blood is a specialized connective tissue consisting of plasma and formed elements: erythrocytes, leukocytes, and platelets. Erythrocytes transport oxygen, leukocytes participate in immune defence, and platelets contribute to haemostasis.[5–7]

Comparative interpretation: Rakta Dhatu has a relatively clear functional point of comparison with modern blood. Nevertheless, the Ayurvedic concept includes theoretical meanings beyond microscopic classification.[1–3, 5–7]

5.3 Mamsa Dhatu

Ayurvedic perspective: Mamsa Dhatu is associated with muscular or flesh-related structures. Within the Ayurvedic framework, it contributes to bodily form, covering, and strength.[1–3]

Modern histological perspective: Modern histology classifies muscle into skeletal, cardiac, and smooth muscle. Skeletal muscle supports movement and posture; cardiac muscle forms the muscular wall of the heart; smooth muscle occurs in many hollow organs and blood vessels.[5–7]

Comparative interpretation: Mamsa Dhatu can be compared broadly with muscular and flesh-related structures. Its exact correspondence with modern muscle types is not established, and it should not automatically be restricted to skeletal muscle alone.[1–3, 5–7]

5.4 Meda Dhatu

Ayurvedic perspective: Meda Dhatu is traditionally associated with adipose material, lubrication, and bodily nourishment.[1–3]

Modern histological perspective: Adipose tissue is a specialized connective tissue composed predominantly of adipocytes. White adipose tissue stores energy, insulates, and participates in endocrine signalling; brown adipose tissue contributes to thermogenesis. Adipose tissue also contains blood vessels, immune cells, and stromal

cells.[5–7]

Comparative interpretation: Meda Dhatu has a broad structural and functional comparison with adipose tissue, but may not correspond exactly to every cellular, metabolic, and endocrine feature of modern adipose tissue.[1–3, 5–7]

5.5 Asthi Dhatu

Ayurvedic perspective: Asthi Dhatu is associated with skeletal structures, bodily support, strength, and structural stability.[1–3]

Modern histological perspective: Bone is a mineralized connective tissue whose matrix contains collagen and mineral components, predominantly hydroxyapatite. Osteoblasts participate in formation, osteoclasts in resorption, and osteocytes in maintenance and regulation. Bone protects organs and provides attachment for muscles.[5–7]

Comparative interpretation: Asthi Dhatu can be compared most directly with the skeleton and bone tissue. Its full Ayurvedic description should be interpreted from original textual context rather than assumed identical to modern bone histology.[1–3, 5–7]

5.6 Majja Dhatu

Ayurvedic perspective: Majja Dhatu is discussed in relation to the internal contents of Asthi and bodily nourishment and function. Its interpretation varies with textual context and classical commentary.[1–3]

Modern histological perspective: Bone marrow is a specialized tissue in medullary cavities and spaces of spongy bone. Red marrow is involved in haematopoiesis, while yellow marrow contains more adipose tissue. Nervous tissue, by contrast, consists of neurons and supporting glial cells.[5–7]

Comparative interpretation: Majja Dhatu is sometimes compared with bone marrow and, in some interpretative discussions, nervous tissue. These correlations are not interchangeable; no universal one-to-one equivalence with either bone marrow or the nervous system is established.[1–3, 5–7]

5.7 Shukra Dhatu

Ayurvedic perspective: Shukra Dhatu is traditionally associated with reproductive capacity and continuation of the reproductive process. Its Ayurvedic interpretation is broader than the name of a single microscopic cell type.[1–3]

Modern histological perspective: The male reproductive system includes seminiferous tubules, Sertoli cells, Leydig cells, and developing germ cells; spermatogenesis produces spermatozoa. The female reproductive system includes ovarian follicles and oocytes. Semen combines spermatozoa with secretions from accessory reproductive glands.[5–7]

Comparative interpretation: Shukra Dhatu can be compared broadly with reproductive biology, but should not be equated exclusively with spermatozoa, semen, or a single modern reproductive tissue. Textual context and commentary are important.[1–3, 5–7]

6. Summary of the Comparative Perspective

Ayurvedic Dhatu	Relevant modern histological concept	Important limitation
Rasa	Plasma, lymph, interstitial fluid, nutrient transport.[5–7]	No single equivalent is established.[1–3]
Rakta	Blood and its formed elements.[5–7]	Ayurvedic functions are broader than microscopic classification.[1–3]
Mamsa	Muscle and flesh-related structures.[5–7]	Exact correspondence with modern muscle types is uncertain.[1–3]
Meda	Adipose tissue.[5–7]	Traditional concept may not cover every modern adipose function.[1–3]
Asthi	Bone and skeletal structures.[5–7]	Classical scope requires textual interpretation.[1–3]
Majja	Bone marrow; proposed comparisons with nervous tissue.[5–7]	These interpretations are distinct and should not be conflated. [1–3]
Shukra	Reproductive cells and physiology.[5–7]	Not identical to spermatozoa or semen alone.[1–3]

This table presents possible areas for comparison, not validated anatomical equivalences.

7. DISCUSSION

Sapta Dhatu Siddhanta is an important component of Ayurvedic understanding of bodily structure and function. The seven Dhatus are described as interrelated constituents that support the body and participate in its maintenance.[1–4]

Modern histology uses a different framework, classifying tissues by microscopic organization, cellular composition, extracellular matrix, and physiological role. Categories include epithelial, connective, muscular, and nervous tissues, alongside specialized tissues such as blood, bone, and adipose tissue.[5–7]

Some Dhatus have areas of structural or functional overlap with modern biological entities. Rakta and blood, Mamsa and muscle, Meda and adipose tissue, and Asthi

and bone are useful examples for further examination.[1–3, 5–7] Other concepts, particularly Rasa, Majja, and Shukra, require careful interpretation because their classical meanings do not map neatly onto a single modern tissue category.

A rigorous comparative review should distinguish three levels of interpretation:

- Textual interpretation: What the classical Ayurvedic text actually describes.[1–3]
- Comparative interpretation: Which modern structures or functions may offer a useful point of comparison.[5–7]
- Scientific validation: Whether a proposed correspondence has been supported by appropriate anatomical, histological, physiological, or experimental evidence.

Similarity in function or terminology alone does not establish that two concepts are identical. Future research should examine classical passages alongside reliable anatomical evidence and avoid imposing modern terminology on traditional concepts without sufficient justification.

8. Research Gaps and Future Scope

- Systematic comparison of Dhatu descriptions in Charaka Samhita, Sushruta Samhita, and Ashtanga Hridaya.[1–3]
- Critical examination of Sanskrit terminology and interpretations provided by classical commentators.[1–3]
- Separate evaluation of proposed correlations between Rasa and body fluids, Majja and bone marrow or nervous tissue, and Shukra and reproductive biology.
- Histological and physiological research into specific hypotheses generated by textual comparison.
- Clear criteria to distinguish conceptual similarity from demonstrable anatomical equivalence.

Such research may improve the academic study of Rachana Sharir and encourage dialogue between Ayurvedic scholarship and modern biomedical science.

9. CONCLUSION

Sapta Dhatu Siddhanta is a fundamental Ayurvedic concept describing seven constituents associated with maintenance and functioning of the human body.[1–3] Modern histology provides a microscopic classification of biological tissues based on cellular and extracellular organization.[5–7]

A comparative review identifies useful areas for discussion, particularly Rakta and blood, Mamsa and muscle, Meda and adipose tissue, and Asthi and bone. Other Dhatus require broader and more context-sensitive interpretations.

The two systems should not be considered identical, and proposed correlations should not be presented as established scientific facts without appropriate evidence. A critical, text-based, and evidence-informed approach is the most reliable foundation for further research.
